

Just as an artificial breeder's power to change a species is limited, so too is the power of natural selection. Biological change has distinct limits

Darwin's finches are a clear example of evolution in action. They have evolved into many different varieties

Seed Eater

Insect Eater

This isn't really *evolution*. Nowhere does this adaptive radiation show that natural selection can produce a new basic type of organism

The Galapagos finches help confirm to me that all birds evolved from flightless dinosaur-like ancestors

The Galapagos Finches

What do YOU think?
